

Why Mathematics - A Formal take on Mathematics

By Nnamdi Michael Okpala

What is Mathematics?

I would define mathematics as 'A **formal system** used to explain phenomena' the world around us'. A phenomena is something in question. Such example are combustions, electrocutions. The term **formal** is derived form the word **form** which means being structured.

A system is collection of components working together. Example of s

These structure/form is rigours and intertwined in the world around us. This abstract constructs are the foundation of creative problem solving merited by the system that the mathematician creates to solve his/her problem. Phenomena can be explain away my many unjustified reason.

However a formal system of reasoning is used in maths and physics to disassemble unjustified claims. The formal systems are construct of how the thing in question works. Mathematics is not just about numbers, it serves a foundation with a diverse set of branch to solve problem in many other domains industry validated by the system it was defined in.

A problem shared is not always a problem solved. Before a problem must be solved it must be defined. We use maths to define ,and solve many problems in our mathematical, physical
